

Merge Engine (functionality test)

merge storage engine is a very simple engine that allows to "merge" multiple identical MyISAM tables. It has largely been superseded by partitioning engine which is more flexible (and works with non-MyISAM engines). The advantages of merge engine:

- partitioning engine requires the partitioning key to be part of primary key. If we divide by filterId, that means that our primary key in Source and Object would have to be composite: (objectId, filterId)
- it is not immediately clear how to turn existing MyISAM tables into partitioned table.

Advantages of partitioning:

- it is more clever, eg, if data is partitioned by filterId and query selects rows by filterId, it'll only examine the partition with a given filterId

The test described below was run on lsst-dbdev5 at ncsa (which has 16 GB of RAM), using 10 Source tables, total size of these table: ~30GB (2.8G, 1.1G, 62M, 6.0G, 4.5G, 164M, 1.5G, 6.2G, 5.7G, 1.3G). So, data does not fit in memory.

```
